# Chapter 10 - C Structures, Unions, Bit Manipulations, and Enumerations

#### **Outline**

- 10.1 Introduction
- 10.2 Structure Definitions
- 10.3 Initializing Structures
- 10.4 Accessing Members of Structures
- 10.5 Using Structures with Functions
- 10.6 typedef
- 10.7 Example: High-Performance Card Shuffling and Dealing Simulation
- 10.8 Unions
- 10.9 Bitwise Operators
- 10.10 Bit Fields
- 10.11 Enumeration Constants

Dr Ashok K Nagawat

# **Objectives**

- In this tutorial, you will learn:
  - To be able to create and use structures, unions and enumerations.
  - To be able to pass structures to functions call by value and call by reference.
  - To be able to manipulate data with the bitwise operators.
  - To be able to create bit fields for storing data compactly.

10.1 Introduction

#### Structures

- Collections of related variables (aggregates) under one name
  - Can contain variables of different data types
- Commonly used to define records to be stored in files
- Combined with pointers, can create linked lists, stacks, queues, and trees

Dr Ashok K Nagawat

#### 10.2 Structure Definitions

• Example

struct card {
 char \*face;
 char \*suit;
};

- struct introduces the definition for structure card
- card is the structure name and is used to declare variables of the structure type
- card contains two members of type char \*
  - These members are face and suit

Dr Ashok K Nagawat

10.2 Structure Definitions

- struct information
  - A struct cannot contain an instance of itself
  - Can contain a member that is a pointer to the same structure type
  - A structure definition does not reserve space in memory
    - Instead creates a new data type used to define structure variables

#### Definitions

- Defined like other variables:

```
card oneCard, deck[ 52 ], *cPtr;
```

- Can use a comma separated list:

```
struct card {
   char *face;
   char *suit;
} oneCard, deck[ 52 ], *cPtr;
```

Dr Ashok K Nagawat

#### 10.2 Structure Definitions

Fig. 10.1) A possible storage alignment for a variable of type struct example showing an undefined area in memory.§

#### 10.2 Structure Definitions

- Valid Operations
  - Assigning a structure to a structure of the same type
  - Taking the address (&) of a structure
  - Accessing the members of a structure
  - Using the sizeof operator to determine the size of a structure

Dr Ashok K Nagawat

# 10.3 Initializing Structures

- Initializer lists
  - Example:
     card oneCard = { "Three", "Hearts" };
- Assignment statements
  - Example:

```
card threeHearts = oneCard;
```

– Could also define and initialize threeHearts as follows:

```
card threeHearts;
threeHearts.face = "Three";
threeHearts.suit = "Hearts";
```

# 10.4 Accessing Members of Structures

- Accessing structure members
  - Dot operator (.) used with structure variables
     card myCard;
     printf( "%s", myCard.suit );
  - Arrow operator (->) used with pointers to structure variables
     card \*myCardPtr = &myCard;
     printf( "%s", myCardPtr->suit );
  - myCardPtr->suit is equivalent to
     ( \*myCardPtr ).suit

```
Fig. 10.2: fig10_02.c
                                                                                                          10
                                                                                         Outline
     Using the structure member and
     structure pointer operators */
4 #include <stdio.h>
                                                                                   fig10_02.c (Part 1 of
6 /* card structure definition */
7 struct card {
     char *face; /* define pointer face */
     char *suit; /* define pointer suit */
10 }; /* end structure card */
12 int main()
13 {
     struct card a; /* define struct a */
     struct card *aPtr; /* define a pointer to card */
     /* place strings into card structures */
     a.face = "Ace";
19
     a.suit = "Spades";
     aPtr = &a; /* assign address of a to aPtr */
                                                                                           Dr Ashok K Nagawat
```

**10.5 Using Structures With Functions** 

- Passing structures to functions
  - Pass entire structure
    - Or, pass individual members
  - Both pass call by value
- To pass structures call-by-reference
  - Pass its address
  - Pass reference to it
- To pass arrays call-by-value
  - Create a structure with the array as a member
  - Pass the structure

10.6 typedef

### • typedef

- Creates synonyms (aliases) for previously defined data types
- Use typedef to create shorter type names
- Example:

typedef struct Card \*CardPtr;

- Defines a new type name CardPtr as a synonym for type struct Card \*
- typedef does not create a new data type
  - Only creates an alias

Dr Ashok K Nagawat

**10.7 Example: High-Performance Card- shuffling and Dealing Simulation** 

#### • Pseudocode:

- Create an array of card structures
- Put cards in the deck
- Shuffle the deck
- Deal the cards

Dr Ashok K Nagawat

```
/* Fig. 10.3: fig10_03.c
                                                                                                   15
                                                                             The card shuffling and dealing program using structures */
                                                                                   Outline

                                                                                                                                                                                                 Dr Ashok K Nagawat
```

10.8 Unions

#### • union

- Memory that contains a variety of objects over time
- Only contains one data member at a time
- Members of a union share space
- Conserves storage
- Only the last data member defined can be accessed

#### • union definitions

```
- Same as struct
    union Number {
        int x;
        float y;
    };
    union Number value;
```

Dr Ashok K Nagawat

20

10.8 Unions

- Valid union operations
  - Assignment to union of same type: =
  - Taking address: &
  - Accessing union members: .
  - Accessing members using pointers: ->

Dr Ashok K Nagawat

```

```

# 10.9 Bitwise Operators

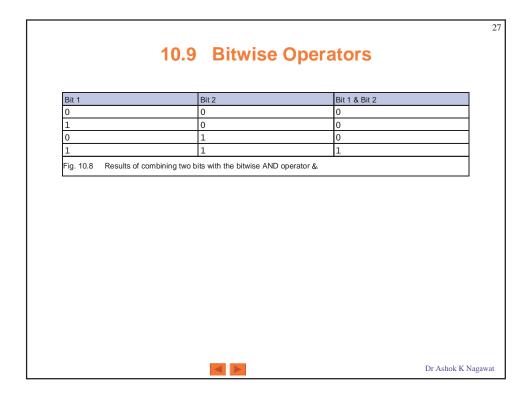

- All data represented internally as sequences of bits
  - Each bit can be either 0 or 1
  - Sequence of 8 bits forms a byte

Operator		Description		
&	bitwise AND	The bits in the result are set to 1 if the corresponding bits in the two operands are both 1.		
I	bitwise inclusive OR	The bits in the result are set to 1 if at least one of the corresponding bits in the two operands is 1.		
٨	bitwise exclusive OR	The bits in the result are set to 1 if exactly one of the corresponding bits in the two operands is 1.		
<<	left shift	Shifts the bits of the first operand left by the number of bits specified by the second operand; fill from the right with 0 bits.		
>>	right shift	Shifts the bits of the first operand right by the number of bits specified by the second operand; the method of filling from the left is machine dependent.		
~	one's complement	All 0 bits are set to 1 and all 1 bits are set to 0.		
Fig. 10.6 The bitwise operators.

# **10.9 Bitwise Operators**

Operator	Associativity	Туре		
() []>	left to right	Highest		
+ - ++! & * ~ sizeof (type)	right to left	Unary		
* / %	left to right	multiplicative		
+ -	left to right	additive		
<< >>	left to right	shifting		
< <= > >=	left to right	relational		
== !=	left to right	equality		
&	left to right	bitwise AND		
٨	left to right	bitwise OR		
1	left to right	bitwise OR		
&&	left to right	logical AND		
П	left to right	logical OR		
?:	right to left	conditional		
= += -= *= /= &=  = ^= <<= >>= %=	right to left	assignment		
,	left to right	comma		
Fig. 10.15 Operator precedence and associativity.				

#### 10.10 Bit Fields

- Bit field
  - Member of a structure whose size (in bits) has been specified
  - Enable better memory utilization
  - Must be defined as int or unsigned
  - Cannot access individual bits
- Defining bit fields
  - Follow unsigned or int member with a colon (:) and an integer constant representing the width of the field
  - Example:

```
struct BitCard {
   unsigned face : 4;
   unsigned suit : 2;
   unsigned color : 1;
};
```

Dr Ashok K Nagawat

40

#### 10.10 Bit Fields

- Unnamed bit field
  - Field used as padding in the structure
  - Nothing may be stored in the bits

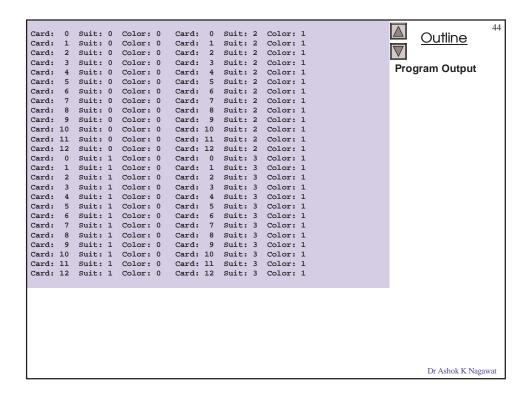

```
struct Example {
  unsigned a : 13;
  unsigned : 3;
  unsigned b : 4;
}
```

 Unnamed bit field with zero width aligns next bit field to a new storage unit boundary

```

```

#### **10.11 Enumeration Constants**

#### • Enumeration

- Set of integer constants represented by identifiers
- Enumeration constants are like symbolic constants whose values are automatically set
  - Values start at 0 and are incremented by 1
  - Values can be set explicitly with =
  - Need unique constant names
- Example:

```
enum Months { JAN = 1, FEB, MAR, APR, MAY, JUN, JUL,
AUG, SEP, OCT, NOV, DEC};
```

- Creates a new type enum Months in which the identifiers are set to the integers 1 to 12
- Enumeration variables can only assume their enumeration constant values (not the integer representations)

Fig. 10.18: fig10\_18.c 46 Using an enumeration type \*/ Outline #include <stdio.h> fig10\_18.c 5 /\* enumeration constants represent months of the year \*/ 6 enum months { JAN = 1, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC ]; 9 int main() 10 { enum months month; /\* can contain any of the 12 months \*/ 11 12 13 /\* initialize array of pointers \*/ const char \*monthName[] = { "", "January", "February", "March", "April", "May", "June", "July", "August", "September", "October", 15 "November", "December" }; 16 17 18 /\* loop through months \*/ 19 for ( month = JAN; month <= DEC; month++ ) {</pre> 20 printf( "%2d%11s\n", month, monthName[ month ] ); } /\* end for \*/ return 0; /\* indicates successful termination \*/ 24 } /\* end main \*/ Dr Ashok K Nagawat
